plot(chlapps.hist)
```

The distribution of the change of log of application number has the appearance of a normal(ish) distribution. There are 2 outlier points with a change of -.1 and +.4 that correspond to Arizona University and Florida State University. There are however no indications that these outliers would affect the regression at this point or that they should be removed.

Which schools had the greatest increase in number of log applications

```
## school chlapps
## 3 arizona 0.3989162
## 1 alabama 0.2064476
## 5 arizona state 0.2062283
## 77 oregon 0.1869907
## 107 villanova 0.1601181
## 61 n.c. state 0.1362371
```

Which schools had the greatest decrease in number of log applications

```

cperf is the variable with the greatest variance, with a value of 0.82425892

```
# Create the model.
change.lapps.model <- lm(chlapps ~ cbowl + cbtitle + cfinfour, data = reshaped.data)</pre>
```

Additional assumptions needed for the model to be causal

One important assumption needed for the model to be causal is the exogeneity of the dependent variables in the model with the error term in the model. Exogeneity can be defined as the requirement that the dependent variables are not related to the error term. Assuming the population model presented:

$$claps_i = \beta_0 + \beta_1 cbowl_i + \beta_2 cbtitle_i + \beta_3 cfinfour_i + a_i + cu_i$$

Exogeneity of the variables in the model can be formulated as:

$$Cov(cbowl_i, cu_i) = Cov(cbtitle_i, cu_i) = Cov(cfinfour_i, cu_i) = 0$$

Additional assumption needed for OLS to consistently estimate the first-difference model

For OLS to consistently estimate the first difference model, we need to assume that assumptions MLR1-MLR4' hold. We also need to assume that the model isn't affected by omitted variable bias, meaning that all the explanatory variables are included in the model. The presence of omitted variables that are correlated with any of the variables in the model creates a bias in the estimation of the coefficients of the variables selected in the model.

In the abscence of a guarantee that we have not left unmeasured effect in the model, a manipulation is needed to make a control variable truly random so that we can estalish the that the bias introduced by any unmeasured variables is null.

```
# Estimate the model
print(summary(change.lapps.model))
```

```

## F-statistic: 2.998 on 3 and 54 DF, p-value: 0.03855
```

The F statistic for the model has a p-value of 0.03855, which is significant at the 0.05 level. The coefficient for the intercept is 0.01684 indicating that the year over year incease in application is 1.6% from 1992 to 1993. However, the t-statistic for that coefficient has a value of 0.1932 and is not significant at the 0.05 level. The coefficient for the cbowl variable is .057, indicating that a win in a bowl the year prior, contributes to a 5.7% increase in applications the subsequent year. The t-statistic for the coefficient is significant at the 0.05 level, with a value of 0.0236 The coefficient for the cbtitle variable is .041, indicating that a win in the men's conference championship in the previous year, translates into an increase of 4.1% year over year from 1992 to 1993. The t-statistic for the coefficient is 0.1950 and is not significant at the 0.05 level. The coefficient for the cfinfour variable is -0.06961 and seems to indicate that an appearance in the men's final four the year prior is related to a decrease of 6.9% of applications.

Question6

The F statistic obtained from the model is the test of overall significance of the model. We have already establish that it has a p-value of 0.03855, which is significant at the 0.05 level. We can obtain the same statistic with the linear Hypothesis function.

```
linearHypothesis(change.lapps.model, c("cbowl", "cbtitle", "cfinfour"))
```

```
## Linear hypothesis test
##
## Hypothesis:
## cbowl = 0
## cbtitle = 0
## cfinfour = 0
##
## Model 1: restricted model
## Model 2: chlapps ~ cbowl + cbtitle + cfinfour
##
     Res.Df
##
                RSS Df Sum of Sq
                                        Pr(>F)
## 1
         57 0.58953
## 2
         54 0.50537
                         0.08416 2.9976 0.03855 *
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
```

Because the model is significant, we do not want to read too much into the t-statistics of each of the coefficients of the model. We had noted that 3 out of 4 coefficients had t-values that were not significant at the 0.05 level. It appears that the combined explanatory power of the model is still relevant, as evidenced by the F-statistic.
